

Axial Piston Variable Pump HP1VO Series 01

Size: 60~260 mL/r Rated pressure: 35 MPa Max. pressure: 40 MPa

Features

- Axial variable pump of swashplate design for hydrostatic drives in open circuits
- For automatic suction, it works with pressurized reservoir or integrated charge pump (centrifugal pump)
- The output flow is proportional to the drive speed and infinitely varied between the maximum value and zero
- Various control options to satisfy different operating requirements
- Power control externally adjustable even during operation of the pump
- The through drive can connect gear pumps and axial piston pumps of up to the same size, i.e. 100% through drive

Working Viscosity

In order for the optimum efficiency and service life, it is recommended to select the working viscosity at working temperature within the range below:

 V_{opt} = optimal working viscosity 16...36 mm 2 /s It is subject to the reservoir temperature of an open circuit.

> Limit Viscosity

Limit viscosity:

Vmin=5mm²/s

Short-term operation(t<3min)

Permissible maximum temperature tmax=+115°C

V_{max}=1600mm²/s

Short-term operation(t<3min)

Cold start(p≤3MPa, n≤1000rpm, tmin=-140°C)

Only for no-load start, it must reach the optimum working temperature in 15 min.

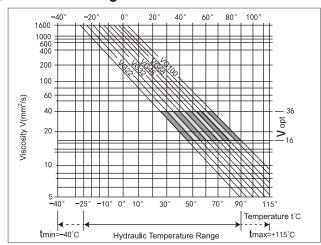

Note:

Local temperature (e.g.: bearing area) shall not exceed the maximum fluid temperature 115 °C. The temperature in the bearing area is no more than 5 K higher than average case drain temperature.

It depends on the pressure and speed.

Take special actions within the range of -40 $^{\circ}\text{C}$ to -25 $^{\circ}\text{C}$ (at cold start). Please consult us for the details.

Selection Diagram

Instructions on Selection of Hydraulic Fluid

The working temperature dependent on the ambient temperature is required for correct selection of hydraulic fluid. It refers to the circuit temperature of a closed circuit and the reservoir temperature of an open circuit.

The hydraulic fluid should be so selected that the working viscosity in the working range is within the optimum range ($V_{\rm opt}$, the shaded area on the selection diagram). The higher viscosity is recommended under the same conditions.

For example:

At an ambient temperature of X $^{\circ}$ C, the working temperature of the circuit is 60 $^{\circ}$ C. The viscosity within the optimum range (V_{opt} ,shaded area) is VG46 or VG68 and the latter should be selected. Note:

The case drain temperature depends on the pressure and speed, and it is always higher than the circuit temperature. The temperature at any point within the system should not exceed +115 °C. Please contact us if the above condition cannot be maintained due to extreme working conditions.

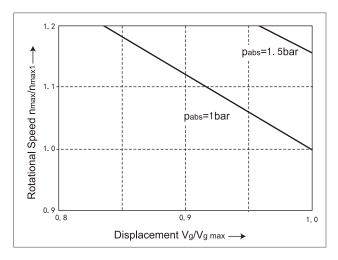

Filtration

Finer filtration improves the cleanliness level of the hydraulic fluid, thus increasing the service life of the axial piston unit. To ensure normal operation of the axial piston unit, a cleanliness level of at least 20/18/15 according to ISO 4406 is to be maintained.

When the hydraulic fluid has a high temperature (+90 $^{\circ}$ C to +115 $^{\circ}$ C), the cleanliness level should at least reach 19/17/14 according to ISO 4406. Please contact us if the above cleanliness level cannot be maintained.

Maximum Permissible Speed (speed limit)

Permissible rotational speed by increasing inlet pressure p_{abs} at suction port S or $V_g \leq V_{g\ max}$

> Working Pressure Range

Input

Absolute pressure at port S

Without charge pump

Pabs min			0.8bar
Pabs max			3Ubar
	 	S E1	

Please consult us if the pressure>5bar.

With charge pump

Pabs min	0 . 6bar
Pabs max	2bar

Output

Pressure at port A or B

Without charge pump

ри	350bar
pmax	400bar

Rated pressure:maximum design pressure when the fatigue strength is guaranteed.

Maximum pressure:permissible maximum working pressure in short time (t<1s).

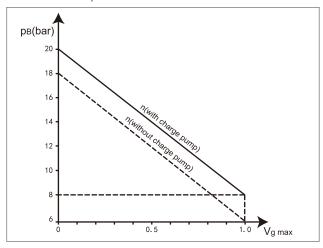

Case Drain Pressure

Case drain pressures at ports T_1 and T_2 may be 1.2bar higher than inlet pressure at port S, but it is no greater than

Minimum Working Pressure

The required minimum working pressure pB $_{\text{min}}$ for pump working lines depends on the rotational speed, swivel angle and displacement (see the table below).

> Oil Seal

Permissible pressure load

The service life of the shaft seal depends on the pump speed and case drain pressure. It is recommended that the average lasting case drain pressure at working temperature is no greater than 3bar absolute pressure (as the speed falls, the maximum permissible case drain pressure is 6bar) and the short-term (t<0.1s) permissible absolute pressure peak may reach 10bar. The service life of the shaft seal decreases with increasing frequency of pressure peaks.

Temperature Range

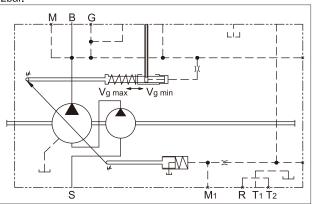

The FKM shaft seal may be used for case temperatures from -25 $^{\circ}$ C to +115 $^{\circ}$ C.

The NBR shaft seal may be used for case temperatures from -40 $^{\circ}\text{C}$ to +90 $^{\circ}\text{C}$.

Note: In applications below -25 °C, an NBR shaft seal is required.

Charge Pump (with impeller)

The charge pump is a circulating pump with which the HP1VAO series can be operated at higher speeds. The charge pump also facilitates cold starting at low temperatures and high viscosity of the hydraulic fluid. Hence, there is no need to pressurize the reservoir in most cases. For use of a charge pump, the maximum permissible reservoir pressure is 2bar.

Case Flushing

The case should be flushed via T1/T2 or R if the variable pump which has a control valve with EP/HD and DR or stroke limiter (U./H.) operates for a long time (t>10min) at zero position or at low pressure (<15bar).

See the table below for the flushing flow:

Size	60	95	115	125	130	145	165	190	260
q _v flush (L/min)	3	4	4	4	4	4	4	5	6

Pumps (HP1VAO) with a charge pump require no flushing as partial boost flow enters the case. Be careful when the case drain flow exceeds the total leakage and control flow of the rotary assembly.

- 1): The values apply at absolute pressure(pabs)=1bar at suction port S and mineral based hydraulic fluids.
- 2) : The values apply at absolute pressure(pabs)≥0.8bar at suction port S and mineral based hydraulic fluids.
- 3) : The values apply at V_g≤V_{g max} or for increased inlet pressure(p_{abs}) at suction port S.
- 4): -The valid range is between 0 and the maximum permissible speed.
 - It is applicable for external excitation (e.g. engine 2 to 8 times rotary frequency, cardan shaft twice the rotary frequency).
 - -The limit value is only valid for a single pump.
 - -The load on the connecting pieces must be considered.

Note: Operation above the maximum values or below the minimum values may result in a loss of function, reduced service life or the destruction of the axial piston unit. The permissible values may be calculated.

> Specification Calculation

Flow $q_v = \frac{V_g \cdot n \cdot \eta_v}{1000}$

[L/min] $V_g = Displacement, mL/r$

 Δp = Differential pressure,MPa

Torque $T = \frac{V_9 \cdot \Delta p}{2 \cdot \pi \cdot \eta_{mh}}$

[Nm] n = Speed,r/min

 η_v = Volumetric efficiency

 $\eta_{mh} = Mechanical-hydraulic efficiency$

Power $P = \frac{2\pi \cdot T \cdot n}{60000} = \frac{q_v \cdot \Delta p}{60 \cdot \eta_t}$ [KW] $\eta_t = \text{Total efficiency}$

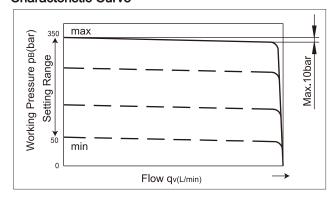

> DR-Pressure Control

DR With pressure cut-off control

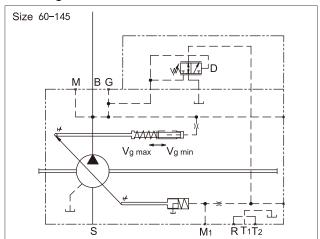

The pressure controller can maintain constant pressure of the hydraulic system within its control range despite changes in the flow. The variable pump only supplies as must hydraulic fluid as required by the actuator. If the working pressure exceeds the set point of the integrated pressure control valve, the pump will automatically swivel back until the pressure deviation is corrected.

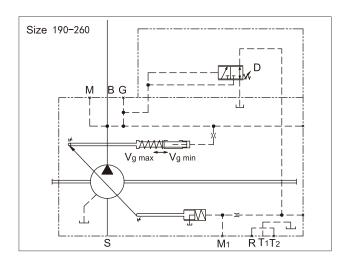

Start position of depressurized state: $V_{g \ max}$ Setting range from 50 to 350 bar.

Characteristic Curve

Circuit diagram

DR-Pressure Control

DRS pressure control with load sensing

The load sensing controller works as a load-pressure controlled flow controller and adjusts the displacement of the pump to the flow required by the actuator.

The flow depends on the cross section of the external metering orifice (1) which is located between the pump outlet and the actuator. The flow is independent of the load pressure below the setting of the power curve and power cut-off and within the control range of the pump.

The metering orifice is usually a separately located load sensing directional valve (control block). The spool position of the directional valve determines the opening cross section of the metering orifice and thus the flow of the pump.

The load sensing controller compares the pressures upstream and downstream of the metering orifice and keeps the pressure drop (differential pressure $\Delta p)$ through the orifice and thus the flow constant.

If the differential pressure Δp at the metering orifice increases, the pump swivels back (toward Vg min).

If the differential pressure Δp falls, the pump swivels out (toward Vg $_{max})$ until equilibrium at the metering orifice is restored.

∆phole = ppump-pactuator

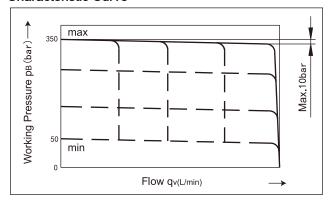

Setting range of Δp : 14 to 25 bar

Setting of standard differential pressure: 18 bar. Please specify in plain text when ordering.

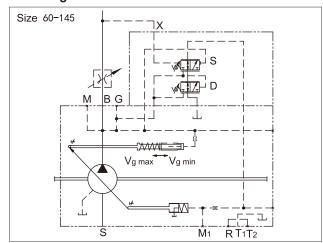

The standby pressure in zero stroke operation (metering orifice closed) is slightly higher than Δp setting.

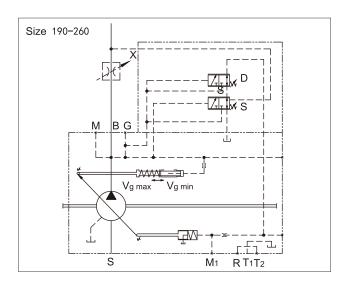

(1)The metering orifice (control block) is not included in the scope of supply of pumps.

Characteristic Curve

Circuit diagram

LR Power Control

The power controller regulates the displacement of the pump depending on the working pressure so that a given drive power is not exceeded at constant drive speed.

pB Vg=constant

pB: working pressure

Vg: displacement

The precise control with a hyperbolic characteristic curve realizes an optimum utilization of available power. The working pressure acts on a rocker via a measuring spool. An externally adjustable spring force counteracts this and it determines the power setting.

If the working pressure exceeds the set spring force, the rocker actuates the control valve and the pump swivels back (toward $V_{g \, \text{min}}$). The length of the rocker is reduced; the working pressure increases at the same rate as the displacement is reduced and it will not exceed the drive power (pB $^{\star}V_{g}$ = constant).

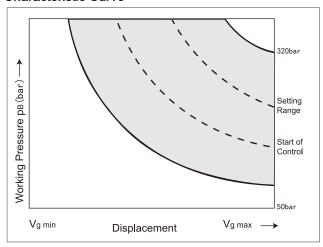

The hydraulic output power (LR characteristic) is influenced by the pump efficiency.

Describe in plain text in turn:

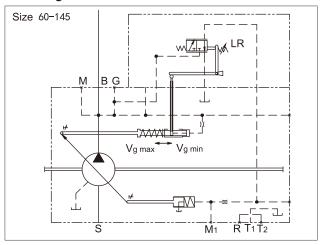

- -drive power P(kW)
- -drive speed n(rpm)
- maximum flow q_v max(L/min)

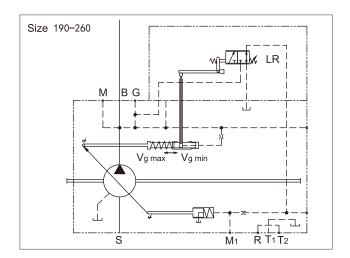

A power diagram is generated based on detailed requirements.

Characteristic Curve

Circuit diagram

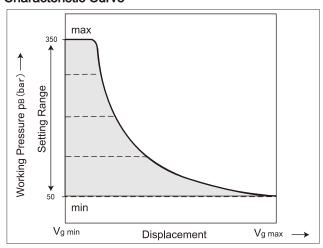

LRD power controller with power cut-off

When it reaches the pressure setting, the pressure cut-off corresponds to the pressure controller that sets pump displacement back to $V_{g\ min}$. It realizes override control of power controller. Namely, the power function is valid when it is below the preset pressure.

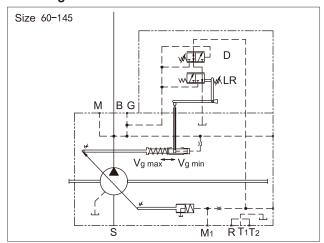

The pressure cut-off function is integrated in the pump control module and preset as required before leaving the factory.

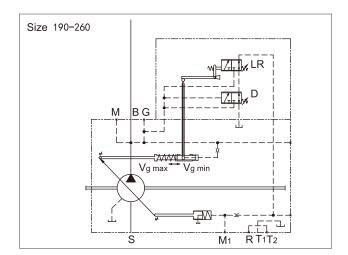

Setting range from 50 to 350 bar

Characteristic Curve

Circuit diagram

LRDS power controller with power cut-off and load sensing

The load sensing controller works as a load-pressure controlled flow controller and adjusts the displacement of the pump to the flow required by the actuator.

The flow depends on the cross section of the external metering orifice (1) which is located between the pump outlet and the actuator. The flow is independent of the load pressure below the setting of the power curve and power cut-off and within the control range of the pump.

The metering orifice is usually a separately located load sensing directional valve (control block). The spool position of the directional valve determines the opening cross section of the metering orifice and thus the flow of the pump.

The load sensing controller compares the pressures upstream and downstream of the metering orifice and keeps the pressure drop (differential pressure Δp) through the orifice and thus the flow constant.

If the differential pressure Δp at the metering orifice increases, the pump swivels back (toward $V_{g\,min}$). If the differential pressure Δp falls, the pump swivels out (toward $V_{g\,max}$) until equilibrium at the metering orifice is restored.

Δphole = ppump-pactuator

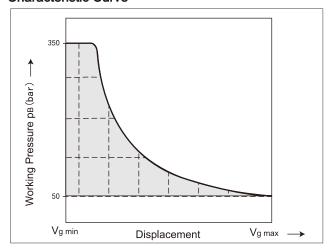

Setting range of 14bar to 25bar

Setting of standard differential pressure: 18 bar. (Please specify in plain text when ordering.)

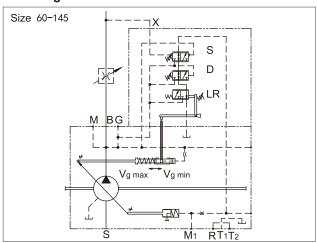

The standby pressure in zero stroke operation (metering orifice closed) is slightly higher than Δp setting.

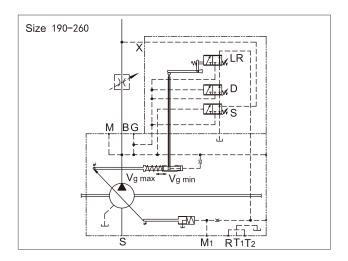

(1) The metering orifice (control block) is not included in the scope of supply of pumps.

Characteristic Curve-H6

ncrease in pilot pressure($V_{g min}$ - $V_{g max}$) Δp =10bar

Circuit diagram

LG1 Pilot pressure negative proportional power control

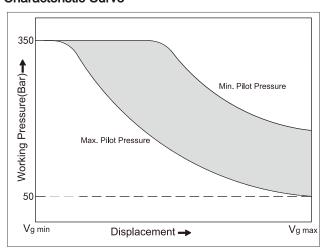

Override control of control settings is realized with external pilot pressure signals. The pilot pressure acts on the adjusting spring for mechanical power control via port Z.

The mechanical power may be regulated by changing the pilot pressure. If the pilot pressure signal is adjusted by load limit control, the power consumption of all actuators will reduce to match the power supplied by the engine.

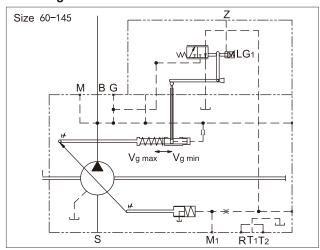

The pilot pressure for power control is supplied by an external control element.

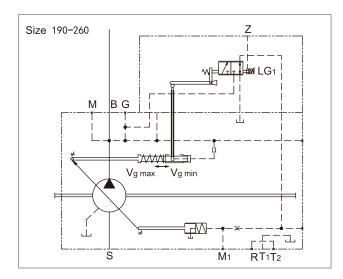

Increase in pilot pressure will reduce power setting.

Characteristic Curve

Circuit diagram

LE1/2 Electrical negative proportional power control

Contrary to hydraulic power control - override control, the basic power setting can be reduced by the electronic pilot current acting on the proportional solenoid. The force thus incurred acts on the adjusting spring for mechanical power control.

The mechanically adjusted basic power setting can be varied via different control current settings.

Increased current = reduced power

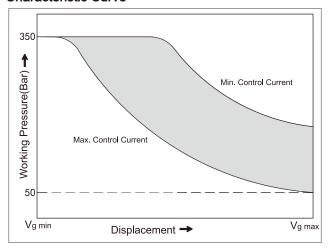

If the pilot current signal is adjusted by load limit control, the power consumption of all actuators will reduce to match the power supplied by the diesel engine.

12V(LE1) or 24V(LE2) power supply is required for controlling proportional solenoids.

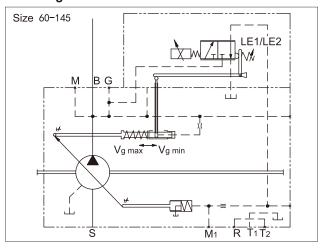

Technical Data-Solenoid

Circuit diagram

➤ EP-Electric Controller with Proportional Solenoid EP1/2 Electrical proportional displacement control

Control from Vg min to Vg max

The pump increases its displacement with increasing control current. Start position without control signal (control current):

- -Vg max at working pressure and external control pressure < 30 bar
- -Vg \min at working pressure and external control pressure > 30 bar

30 bar control pressure is required for the pump to move from its initial position $V_{\text{g max}}$ to $V_{\text{g min}}.$

The required control pressure comes from the load pressure or external control pressure at port G.

An external control pressure of approx. 30 bar is required at port G to e nsure control even at low working pressure (< 30 bar). Note:

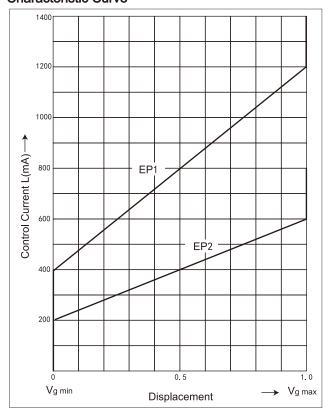

Remove the shuttle valve if no external control pressure is connected to port G.

Install a pump with EP controller in the reservoir only when the hydraulic fluid of mineral oils is used and the reservoir temperature is up to 80 °C.

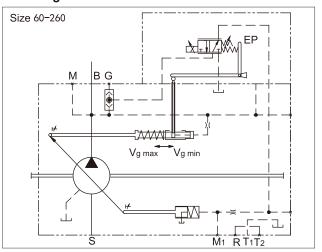

Technical Data-Solenoid

		EP1	EP2	
Voltage		12V (±20%)	24V (±20%)

Connector for Solenoids

DEUTSCH DT04-2P-EP04, 2 pin

molded, without bidirectional suppressor diode(standard)_____I

Type of protection according to DIN/EN 60529: IP67 and IP69K

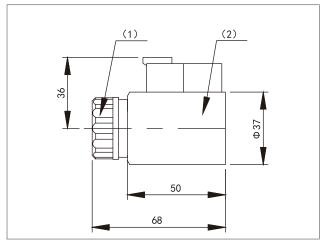

Circuit diagram symbol

Mating connector

DEUTSCH DT06-2S-EP04

The mating connector is not included in the delivery contents.

Note for round solenoids:

The position of the connector can be changed by turning the solenoid body. Proceed as follows:

- 1.Loosen fixing nut (1)
- 2.Tum the solenoid body (2) to the desired postion
- 3. Tighten the fixing nut

Tightening torque of fixing nut: 5⁺¹ Nm

(width across the flats WAF26, 12kt DIN 3124)

Installation Instructions

General

The axial piston unit must be always be filled with hydraulic fluid and air bled during commissioning and operation. This must also be observed following a longer standstill as the system may empty via the hydraulic lines.

The leakage in the housing must be directed to the reservoir via the highest drain port (T1/T2). The minimum suction pressure at port S must not fall below 0.8 bar absolute pressure (without charge pump) or 0.6 bar (with charge pump).

Under all operating conditions, the suction line and case drain line must flow into the reservoir below the minimum fluid level.

Above-reservoir installation

Pump above the minimum fluid level of the reservoir.

Observe the maximum permissible suction height ha min=800mm.

HP1VAO (with charge pump) is not designed to be installed above the reservoir. Recommendation for installation position 7 (shaft upwards): The check valve in the drain line (cracking pressure: 0.5 bar) can prevent draining inside the housing.

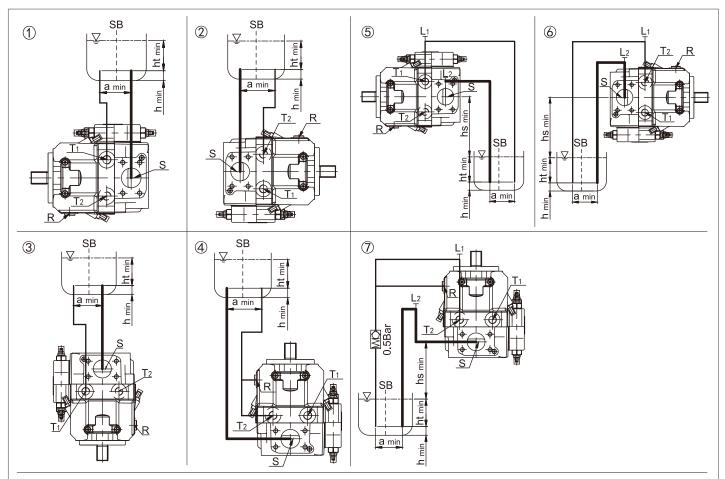

For control options with pressure controller, displacement limiter and EP controller, the minimum displacement setting must be Vg≥5%Vg max.

Below-reservoir installation (standard)

Pump below the minimum fluid level of the reservoir. Recommended installation positions: 1 and 2.

Installation position

See the examples below. Other installation positions may be provided as required.

hs max=800mm, ht min=200mm, h min=100mm, SB=Silencer plate (baffle plate)

When designing the tank, ensure adequate space amin between the suction line and the case drain line to prevent the heated, returned fluid from being directly drawn back out.

Installation Position	Air Bleeding	Filling
1	T ₁	S+T1
2	R	S+T2
3	T1/T2	S+T1/T2
4	R	S+T1/T2

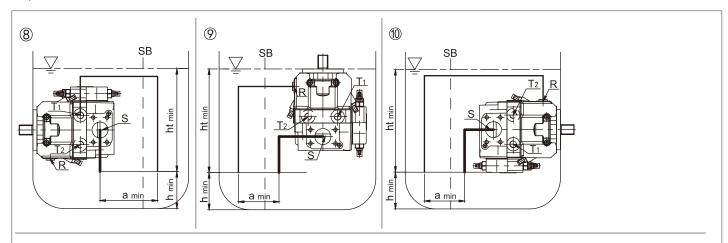

Installation Position	Air Bleeding	Filling
5	L1+L2	L2(S)+L1(T1)
6	R+L2	L2 (S) +L1 (T2)
7	L1+L2	L2(S)+L1(T1/T2)

Installation Instructions

Tank installation

Pump below the minimum fluid level in the tank.

ht min=200mm, h min=100mm, SB=Silencer plate (baffle plate)

When designing the tank, ensure adequate space amin between the suction line and the case drain line to prevent the heated, returned fluid from being directly drawn back out.

Installation Position	Air Bleeding	Filling
8	T ₁	automatically via all open T1, T2, R and S
9	R	ports, though position below the hyraulic fluid
10	R	leve

HP1VO is designed to be used in open circuits.

Project planning, assembly and commissioning of the axial piston unit require the involvement of qualified personnel.

The service line ports and function ports are only designed to accommodate hydraulic lines.

During and shortly after operation, there is a risk of burns on the axial piston unit and especially on the solenoids. Take appropriate safety measures (e. g. by wearing protective clothing).

Depending on the operational state of the axial piston unit (operating pressure, fluid temperature), the characteristic may shift.

Pressure ports:

The ports and fixing threads are designed for the specified maximum pressure. The machine or system manufacturer must ensure that the connecting elements and lines correspond to the specified operating conditions (pressure, flow, hydraulic fluid, temperature) with the necessary safety factors. The data and notes contained herein must be adhered to.

The following tightening torques apply:

Threaded hole for axial piston unit:

The maximum permissible tightening torques Mg max are maximum values for the threaded holes and must not be exceeded.

For values, see the following table.

Fittings:

Observe the manufacturer's instruction regarding the tightening torques of the used fittings.

Fixing screws:

For fixing screws according to DIN 13, we recommend checking the tightening torque individually according to VDI 2230.

Locking screws:

For the metal locking screws supplied with the axial piston unit, the required tightening torques of locking screws Mv apply. For values, see the following table.

The product is not approved as a component for the safety concept of a general machine according to DIN EN ISO 13849.

Thread size		Max. permissible tightening torque of the screw thread MGmax	Required tightening torque for locking screws Mv	WAF Hexagon socket	
M12x1.5	DIN 3852	50Nm	25Nm	6mm	
M14x1.5		80Nm	35Nm	6mm	
M22x1.5		210Nm	80Nm	10mm	
M26x1.5		230Nm	120Nm	12mm	
M33x2		540Nm	310Nm	17mm	

Since 2002

Over twenty years of deep cultivation in the field of hydraulic Solutions

HYTEK is a high technology enterprise integrating R&D, production, sales and service of hydraulic power products. Provides professional hydraulic transmission control products and solutions for construction machinery, road machinery, material handling machinery, agricultural and forestry machinery, industrial equipment and other fields. After more than 20 years of continuous R&D, technological innovation, market development and application services, technical level and the scale of production and sales have been on the forefront of the industry. Hytek has been committed to helping the development of subdivided industries with innovative hydraulic technology, "focusing on the challenges and pressures of customers, providing competitive products and solutions, reducing costs and increasing efficiency for customers, and continuously creating maximum value".
